Anomaly

Source / metric	tceq / Nitrogen dioxide (no2)
Observed / expected baseline	18.8 / 6.01223 ppb
Baseline method	mean of the preceding 7 days of this series (Z-score detector)
Time	2026-07-15 21:00 UTC
Location	29.6863, -95.2947
Severity	severe
Detectors	zscore, stl, isolation_forest

Stored evidence summary

The three tables in this section are look-up tables. You never have to read them through: they are here for the moment a claim quotes a number and you want to check it.

Claims

Mark exactly one box per claim: V (Valid), I (Invalid), or U (Unsure). To skip a claim, leave all three boxes blank; a blank is recorded as missing and never turned into Unsure. Each claim appears exactly once, and the number printed next to it is how I'll refer to that claim if I need to ask you about it.

Label definitions, from the labeling guide

Valid (V): the claim holds up at the precision it states, and the evidence in the packet supports it.

Invalid (I): the evidence in the packet contradicts the claim, the claim misstates a measurement, or the physical reasoning does not hold.

Unsure (U): you cannot tell from what is shown. This covers thin evidence, measurements that cannot resolve the claim, ambiguous wording, and anything outside what you are comfortable judging.

Missing or thin evidence means Unsure, not Invalid.

A cause that is plausible but unproven stays Unsure unless the evidence actually contradicts it.

Some claims bundle several statements into one sentence. Judge those by their parts. If every part earns the same verdict, use that verdict.

Claim 1 of 36

On July 15, 2026, at 21:00 UTC, nitrogen dioxide concentrations at the TCEQ monitor in Houston spiked to 18.8 ppb, representing a severe statistical anomaly relative to expected levels.

Mark exactly one:	☐ V	☐ I	☐ U
-------------------	----------------------------	----------------------------	----------------------------

Note (optional):

Claim 2 of 36

Regional photochemical accumulation is contradicted because openweather reported complete cloud cover near 21:00 UTC and openaq ozone remained very low at the anomaly location, conditions inconsistent with strong sunlight-driven ozone production as the main cause of the severe NO2 enhancement.

Mark exactly one:	☐ V	☐ I	☐ U
-------------------	----------------------------	----------------------------	----------------------------

Note (optional):

Claim 3 of 36

Meteorological trapping is supported because winds near the anomaly were very weak, with 0.0 m/s at the nearest asos station and 0.45 m/s in openweather at about 21:00 UTC, and because gfs indicated a shallow planetary boundary layer of about 114 m at 18:00 UTC, all of which would limit dilution of local NO2 emissions.

Mark exactly one:

☐ V

☐ I

☐ U

Note (optional):

Claim 4 of 36

Regional photochemical ozone-smog buildup is an unlikely primary cause of the NO2 spike because ozone near the anomaly was extremely low at the event time despite warm conditions, indicating the NO2 enhancement was dominated by fresh local emissions and titration instead of oxidized afternoon regional air.

Note (optional):

Claim 5 of 36

The openaq ozone sensor located 0.01 km from the anomaly site measured 0.002 ppm at 2026-07-15T21:00:00+00:00.

Note (optional):

Claim 6 of 36

Near-zero surface wind speeds recorded by ASOS and OpenWeather around 21:00 UTC on July 15, 2026, support horizontal atmospheric stagnation as a key factor in accumulating NO₂ detected by TCEQ.

Mark exactly one:

☐ V

☐ I

☐ U

Note (optional):

Claim 7 of 36

A fresh local combustion plume is supported because the anomalous tceq NO₂ concentration reached 18.8 ppb at 2026-07-15 21:00 UTC while co-located ozone was only 0.002 ppm at the same time, a combination consistent with recently emitted NO titrating ozone near a source rather than aged regional pollution.

There is no evidence to suggest that other air pollutants, such as CO, SO₂, or O₃, contributed to the anomaly.

Note (optional):

Claim 15 of 36

Coincident near-surface ozone concentrations fell to 0.002 ppm at 21:00 UTC on July 15, 2026, indicating ozone titration by primary nitric oxide under suppressed photolysis conditions.

Mark exactly one:

☐ V

☐ I

Note (optional):

Claim 16 of 36

OpenWeather reports of 100 percent cloud cover support diminished solar irradiance, which reduced photochemical photolysis of NO₂ and corresponds with low surface ozone values observed by OpenAQ.

Mark exactly one:

Note (optional):

Claim 17 of 36

Surface meteorological conditions during the anomaly were characterized by calm wind speeds and dense cloud cover, restricting atmospheric dispersion.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 18 of 36

The air-quality chemistry at 2026-07-15 21:00 UTC is most consistent with a fresh local combustion plume because NO₂ was elevated while nearby ozone was only 0.002 ppm, indicating ozone titration by newly emitted NO_x rather than regional photochemical accumulation.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 19 of 36

High cloud cover and depressed ambient ozone levels suppressed the photochemical degradation of NO₂, facilitating its accumulation at the monitoring site.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 20 of 36

The anomaly is a result of a combination of factors including high temperatures, low humidity, and stagnant atmospheric conditions, leading to poor air mixing and increased pollutant concentrations.

Note (optional):

Claim 24 of 36

A fresh nearby combustion emission plume from mobile traffic, diesel equipment, rail, marine, or industrial combustion is a likely cause of the severe NO₂ spike because the monitor recorded 18.8 ppb NO₂ against an expected 6.0 ppb while co-located ozone was only 0.002 ppm, which is a classic near-source NO titration signature rather than aged regional pollution.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 25 of 36

Stagnant atmospheric conditions, characterized by near-zero wind speeds and a low planetary boundary layer height, restricted pollutant dispersion and trapped NO₂ near the ground.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 26 of 36

Meteorological conditions favored temporary trapping of local emissions because near-anomaly surface winds were extremely weak around the event and the modeled planetary boundary layer height was only about 114 m at 18:00 UTC.

Mark exactly one:☐ V☐ I☐ U**Note (optional):**

Claim 27 of 36

Weak dispersion and boundary-layer trapping are a likely cause of the elevated NO₂ concentration because winds near the anomaly were very light at about 0.0 to 0.45 m/s and the modeled planetary boundary layer height was low at about 114 m, conditions that favor accumulation of locally emitted NO_x near the surface.
